A positive approach to psoriasis and psoriatic arthritis
What are the aims of this leaflet?
This leaflet has been written to help you understand more about different types of pustular psoriasis, as well as suitable treatments.

What is psoriasis?
Psoriasis (sor-i’ah-sis) is a long-term (chronic) scaling disease of the skin, which affects around 2% of the UK population. It is not contagious. It appears as red, raised, scaly patches known as plaques. Any part of the skin surface may be involved, but the plaques most commonly appear on the elbows, knees and scalp. It can be itchy, but is not usually painful. Nail changes, including pitting and ridging, are present in 40% to 50% of people with psoriasis and around 30% of people with psoriasis will develop psoriatic arthritis. There are many different types of psoriasis, including chronic plaque psoriasis, types of pustular psoriasis (all of which are described in this leaflet), guttate psoriasis, scalp psoriasis, flexural psoriasis, napkin psoriasis, nail psoriasis and erythrodermic psoriasis (a rare, serious condition which can affect the whole body) – see our What is Psoriasis?, Scalp Psoriasis and Nail Psoriasis leaflets.

What happens?
Normally a skin cell matures in 21 to 28 days and during this time it travels to the surface, where it is lost in a constant invisible shedding of dead cells. In patches of psoriasis the turnover of skin cells is much faster, around 4 to 7 days, and this means that even live cells can reach the surface and accumulate with dead cells. The extent of psoriasis, and how it affects an individual, varies from person to person. Some may be mildly affected, with a tiny patch hidden away which does not bother them, while others may have large visible areas of skin involved that significantly affect daily life and relationships. The process is the same wherever it occurs on the body.

Pustular psoriasis
Pustular psoriasis looks different to plaque psoriasis, although plaque and pustular psoriasis can coexist or one may follow the other. The main distinguishing feature of pustular psoriasis is the appearance of pus spots surrounded by or on top of areas of red skin. This does not mean there is infection present. The
spots simply show that the skin has been invaded by white blood cells. The person is not infected and neither are they contagious in any way.

Pustular psoriasis flare-ups can be triggered by some medicines, irritating substances on the skin, ultraviolet light overdoses, pregnancy, systemic steroids (especially sudden withdrawal of tablet or high-potency topical steroids), infections or emotional stress.

Generalised pustular psoriasis

Generalised pustular psoriasis is a rarer and more serious form of the condition. It is particularly rare in children. It can occur abruptly, sometimes precipitated by the triggers mentioned above, and it can make the person feel quite unwell with fever, shivers, intense itching, rapid pulse, exhaustion, headache, nausea, muscle weakness and/or joint pain. In this condition, the pustules, redness and skin peeling can occur all over the body and, as such, people are normally admitted to hospital for treatment under the care of a dermatologist until it settles down. The skin can be very sore and fragile. Sometimes these attacks are followed by milder outbreaks of psoriasis. Please do note that this is a rare form of the condition.

Palmar-plantar pustulosis (PPP)

Palmar-plantar pustulosis (PPP – also sometimes spelled as palmoplantar psoriasis) is a localised form of psoriasis which affects the palms and/or soles of the feet. Evidence suggests that it tends to occur in people between the ages of 20 and 60, and is more common in people who smoke. Infection and stress are suspected trigger factors. PPP is normally recognisable by large yellow pustules up to 5mm in diameter in the fleshy areas of hands and feet, such as the base of the thumb and the sides of the heels. It may be painful. The pustules dry up and turn a brown colour and then gradually diminish. PPP is usually cyclical though, with new crops of pustules being followed by periods of low activity. This form of psoriasis affects approximately 5% of people with psoriasis. It tends to go in cycles of: erythema (reddening of the skin) followed by formation of pustules and then scaling of the skin. Sometimes the skin can crack, which can cause discomfort, and occasionally there is a degree of functional disability.
Acrodermatitis continua of Hallopeau

Acrodermatitis continua of Hallopeau is another rare type of palm-plantar pustular psoriasis. It is characterised by skin lesions on the ends of the fingers, including the nails which can sometimes become completely destroyed, and sometimes on the toes. The eruption sometimes starts after localised physical trauma. Often the lesions are painful and disabling, with the nails deformed, and bone changes may occur. This condition is quite hard to treat satisfactorily.

Treatment

These conditions are not common and are difficult to treat, so whether the pustular psoriasis is localised or generalised, treatment should be overseen by a dermatologist.

Pustular psoriasis

If you are admitted to hospital with generalised pustular psoriasis, the main aim of treatment is to restore the skin’s barrier function, prevent further loss of fluid, stabilise the body’s temperature and restore the skin’s chemical balance. Imbalances, which can occur, might put added strain on the heart and kidneys, especially in older people. Because of possible complications with this form of psoriasis, if you’re affected you should seek medical care immediately. The likelihood of hospitalisation for a short period of time depends on the severity of the outbreak. When in hospital, bed rest, bland emollient therapy, rehydration and avoiding excessive heat loss can improve the situation. It is important to remove as many of the potential trigger factors as possible, for example suspect medicines. In severe cases, where the patient has become exhausted, other medications may be needed.

To control pustular psoriasis for the longer term, a tablet or injection treatment is usually required. Methotrexate is the most common treatment; ciclosporin is also used if your doctor needs to control the symptoms quickly. Oral steroids are often prescribed for those who do not respond to other forms of treatment or who have become very ill, but their use would be for a brief period only. PUVA (the photosensitising drug psoralen plus UVA light) may also be used once the...
condition has settled down. See our *Psoriasis and Phototherapy* leaflet to find out more about PUVA. In some instances biologic injection treatments may be used, but these are not licensed for pustular psoriasis.

### Palmar-plantar pustulosis (PPP) treatment options

This type of psoriasis can be particularly difficult to treat. First-line treatment usually involves topical therapies, such as potent or super-potent steroids, being applied to the palms and/or soles. Sometimes creams containing coal tar or salicylic acid may be prescribed to help with scaling. The regular application of an emollient can help prevent skin from cracking and keep the palms and soles more supple. It may be beneficial to wear cotton gloves for certain periods during the day, to prevent the treatments rubbing off and to allow the person to continue to use their hands.

Frequent use of topical therapies on the hands and feet can be impractical for most people as it makes working and daily chores difficult. For this reason, localised light treatment (PUVA) or tablet treatments such as methotrexate are often advised.

Although not completely proven, for those who smoke, quitting appears to help reduce the instances and severity of palmar-plantar psoriasis.

Acrodermatitis continua of Hallopeau tends to be resistant to both topical and systemic treatments for psoriasis, so combinations of therapy may be tried. Most episodes of pustular psoriasis will last for a few weeks then disappear or remit to erythrodermic psoriasis.

### Summary

- Pustular psoriasis is a rare form of psoriasis
- Severe cases need urgent referral to a specialist and often hospital admission
- PPP is more common in people who smoke
- PPP and pustular psoriasis flares tend to go in cycles
- The pustules are not an infection but a collection of white cells
- Pustular psoriasis is not contagious.

The Information Standard scheme was developed by the Department of Health to help the public identify trustworthy health and social care information easily. At the heart of the scheme is the standard itself – a set of criteria that defines good quality health or social care information and the methods needed to produce it. To achieve the standard, organisations have to show that their processes and systems produce information that is:

- accurate
- impartial
- balanced
- evidence-based
- accessible
- well-written.

The assessment of information producers is provided by independent certification bodies accredited by The United Kingdom Accreditation Service (UKAS). Organisations that meet The Standard can place the quality mark on their information materials and their website - a reliable symbol of quality and assurance.
The charity for people with psoriasis and psoriatic arthritis

PAPAA, the single identity of the Psoriatic Arthropathy Alliance and the Psoriasis Support Trust.

The organisation is independently funded and is a principal source of information and educational material for people with psoriasis and psoriatic arthritis in the UK.

PAPAA supports both patients and professionals by providing material that can be trusted (evidence-based), which has been approved and contains no bias or agendas.

PAPAA provides positive advice that enables people to be involved, as they move through their healthcare journey, in an informed way which is appropriate for their needs and any changing circumstances.
