What is Psoriatic Arthritis?

A positive approach to psoriasis and psoriatic arthritis
What are the aims of this leaflet?

This leaflet has been written to help you understand psoriatic arthritis, the ways in which it is different from other forms of arthritis, and the treatments available.

What is psoriasis?

Psoriasis (sor-i’ah-sis) is a long-term (chronic) scaling disease of the skin, which affects about 2% of the UK population. It usually appears as red, raised, scaly patches known as plaques. Any part of the skin surface may be involved but the plaques most commonly appear on the elbows, knees and scalp. It can be itchy but is not usually painful. Nail changes, including pitting and ridging, are present in 80% to 90% of people with psoriatic arthritis (this falls to 40% of those with psoriasis alone). Up to 30% of people with psoriasis will develop psoriatic arthritis. There does not seem to be any link between the severity of the psoriasis affecting the skin and the psoriatic arthritis.

What happens in psoriasis?

Normally a skin cell matures in 21 to 28 days and during this time it travels to the surface, where it is lost in a constant invisible shedding of dead cells.

In patches of psoriasis the turnover of skin cells is much faster, around 4 to 7 days, and this means that even live cells can reach the surface and accumulate with dead cells. The extent of psoriasis and how it affects an individual varies from person to person. Some may be mildly affected with a tiny patch hidden away on an elbow which does not bother them while others may have large visible areas of skin involved that significantly affect daily life and relationships. This process is the same wherever it occurs on the body. Psoriasis is not contagious. For more detailed information on psoriasis see our leaflet What is Psoriasis? or visit our website.
What happens in psoriatic arthritis?

Psoriatic arthritis (PsA) is a form of arthritis affecting individuals with psoriasis.

- Joints become inflamed, which causes pain, swelling and stiffness.
- Tendons may also become inflamed and cause pain (often around the heel or in the elbow).
- Joints are typically stiff after resting, particularly early in the morning or in the evening.
- Up to 30% of those with psoriasis may develop some form of arthritis.
- In most people (80%) the arthritis develops after the appearance of psoriasis.
- Some people may develop a condition of the eye (uveitis) which may cause redness and inflammation. If you are concerned about this, seek medical advice.
- People with psoriatic arthritis often complain of feeling fatigued or exhausted.
- There is some evidence that people with psoriasis and/or psoriatic arthritis might have a slightly increased cardiovascular risk (heart disease). See our Psoriasis and the Heart leaflet.

How do joints and tendons become inflamed?

The function of a joint is to allow movement to occur between bones. In the joint, the end of the bone is covered with cartilage, around which is a capsule lined by a membrane called synovium.

This membrane makes the fluid that lubricates the joint space, allowing movement. In arthritis the synovial membrane becomes inflamed and releases substances that cause inflammation.

The inflamed synovium releases more fluid than normal and so the joint becomes tender and swollen. Persistent inflammation may lead to damage to the cartilage and erosion of the underlying bone.
The synovial membrane also lines and lubricates tendons, so overproduction of synovial fluid can also cause tendon inflammation.

What is different about psoriatic arthritis?

There are several features that distinguish psoriatic arthritis from other forms of arthritis.

- The pattern of joints that may be involved is different.
- Psoriatic arthritis may just affect a small number of joints (oligoarthritis) or many joints (polyarthritis). Most commonly the psoriatic arthritis is asymmetric in pattern (unlike rheumatoid arthritis, which is symmetrical).
- Psoriatic arthritis may affect the end joints of fingers, often corresponding with the fingers that have psoriatic nail involvement. See our Nail Psoriasis leaflet.
- When psoriatic arthritis affects the joints of the spine and sacroiliac joints it is called spondylitis (similar to ankylosing spondylitis). This can result in stiffness and pain of the back or neck.
- An entire toe or finger can become swollen or inflamed (dactylitis).
- Some people have involvement of the jaw.
- Psoriatic arthritis may affect where the tendons connect to the bone (enthesitis). Common areas to be affected include the heel and ankle.
- Psoriatic arthritis may cause joints to become stiff and limit their range of movement. In some severe cases the joint may fuse, with the result that it cannot be moved.
- Importantly, the absence of rheumatoid factor in the blood helps distinguish psoriatic arthritis from rheumatoid arthritis.

Distinguishing features are not always present and the individual may have swelling of a few or many joints similar to other types of arthritis, making diagnosis difficult.

At what age and who does psoriatic arthritis affect?

- It may come on at any age.
- It is uncommon in children.
- Usually (in 80% to 90% of cases) the psoriatic arthritis comes on after the psoriasis.
Men and women are equally affected.

60% of men will develop arthritis of the spine as opposed to 40% of women.

What is the outlook in psoriatic arthritis?

- Although psoriatic arthritis cannot be cured at present, many effective treatments exist.
- Treatments will depend on the severity of the disease, with some individuals having minimal arthritis while others are more severely affected.
- Psoriatic arthritis is a chronic condition that may wax and wane.
- Early diagnosis is essential in order to identify those who may develop more severe psoriatic arthritis and begin treatment that can prevent damage occurring to the joints.
- Only a small minority of individuals will go on to develop severe and widespread joint damage.
- Joints that are initially involved in psoriatic arthritis are usually the ones that continue to cause the problems at a later stage, though this is not always the case.
- Genetic markers to identify individuals with potentially more severe arthritis are now becoming practical and will help in reflecting the most suitable type of treatment.

What is the treatment for psoriatic arthritis?

Although psoriatic arthritis is a chronic condition with no cure, there are many effective treatments to manage and control it. Some treatments for psoriatic arthritis may also help psoriasis of the skin. See our What is Psoriasis? leaflet for further information.

Your psoriatic arthritis is likely to be managed by a number of healthcare professionals, which may include:
- your general practitioner (GP)
- a rheumatologist (joint specialist)
- a dermatologist (skin specialist)
- a specialist nurse
- a physiotherapist
- an occupational therapist
- a podiatrist (foot care)
- an ophthalmologist (eye specialist)
- a surgeon (joint replacement).

You may also be referred for specialist tests and imagery. These may include, when appropriate, X-rays, magnetic resonance imaging (MRI), ultrasound etc.

Depending on your individual circumstances you may be offered some of the following different types of treatments.

- Topical analgesic creams for the treatment of mild to moderate pain caused by arthritis.
- Topical medications for skin psoriasis such as vitamin D derivatives, although they may help the skin, have not been shown to benefit joints.
- NSAIDs (non-steroidal anti-inflammatory drugs) work by blocking the production of some of the body’s chemicals that cause inflammation and pain.
- DMARDs (disease-modifying anti-rheumatic drugs) are often prescribed in addition to NSAIDs to help slow down the biological processes that cause the persistent inflammation.
- Corticosteroids as joint injections can be very effective, although these do not work equally well in all individuals. They are safe when used in moderation and with precision.
- Biologics (such as anti-TNF drugs) are a newer group of drugs which may be offered if you do not respond effectively to other DMARDs. They act by mimicking the effects of substances made naturally in the human immune system.

Medical advice is vital about medications that can control inflammation and joint damage.

A severely inflamed joint should be treated with a period of rest followed by exercise (under medical supervision). Physiotherapy of joints and muscles which have stiffened can help prevent loss of movement. See our Physiotherapy & Exercise: Psoriatic Arthritis leaflet.
Remember: all treatments may have unwanted side effects or require special precautions (e.g., during pregnancy). Always make sure you have all the information before embarking on any course of therapy; this includes reading the patient information leaflets (PIL) provided with your medicines.

**Does diet make a difference?**

- No particular diet is uniformly effective; some people with psoriatic arthritis have found cutting down on saturated fats helps and may reduce the doses needed of other treatments, though research has not confirmed this.
- Dietary supplements such as evening primrose oil and certain fish oils may have a variable effect. They are safe and have other health benefits, but effects specifically beneficial to psoriatic arthritis have not been proven in research.
- Following guidelines about healthy lifestyle, keeping weight down and moderating alcohol intake are all generally accepted as beneficial regardless of having psoriasis or psoriatic arthritis.

Remember: many so-called cures for arthritis are not proven by clinical trials to be of use and may be driven by profit to those advocating them.

**Does climate make a difference?**

- Ultraviolet light helps psoriasis in some cases, otherwise climatic conditions such as the weather have a minor role to play; those whose skin and joints wax and wane together are usually better in summer than winter.

**Does the severity of skin or nail psoriasis matter?**

- In 80% of individuals with psoriatic arthritis, nail changes are found compared with only 40% in those with psoriasis alone.
- Nail changes include pitting and discolouration of the nail due to abnormalities in the growth of tissue in the nail bed.
- The risk of developing psoriatic arthritis is greater in individuals with severe psoriasis, yet severe psoriatic arthritis may occur with minimal skin disease.
Do we know what causes psoriatic arthritis?

- The cause of psoriatic arthritis is the subject of much research.
- You cannot catch psoriatic arthritis or psoriasis from someone else. Therefore they are not contagious.
- The cause of psoriatic arthritis is not proven but experts believe it to be a combination of genetic, immunological and environmental factors. 40% of people with psoriasis or psoriatic arthritis have a first-degree relative with the condition. This means you have a higher chance of developing psoriasis or psoriatic arthritis if you have a relative who has the condition. Some experts believe infections such as streptococcal infections may provoke the psoriatic arthritis, though this is not proven.
- Trauma and stress may be contributing factors, although this is not proven.
- The genetic make-up of an individual is likely to determine the risk of developing psoriasis and psoriatic arthritis and probably influences the severity.
- There are certain genetic markers linked to the immune system which are now being used to predict the severity of psoriatic arthritis.
- Much more is known about the mechanisms that lead to inflammation in other conditions and it is likely advances in science will lead to much more effective treatments with fewer side effects.

Where can I get more information?

Around 86% of UK adults have access to the internet – which is the easiest place to find more information. For those who do not have or cannot access online, the options are becoming limited. A good place to start is the local public library, which often holds useful information. It may not be on immediate display, however, so try asking at the main desk. It is also worth asking your local GP surgery or hospital, which should have information in an accessible format.

Can I get financial support?

Many people worry about what happens if they cannot work or need financial help because of the effects of psoriatic arthritis. Fortunately for many, with good therapy and management the condition can be controlled and allow for a
full and active working life. But if you do find that even for a short period of time you are likely to need help, visit the national government websites online. If it is easier, contact your local government or council office, where you should be directed to the appropriate resource and information.

**Useful contacts**
For information about health matters in general and how to access services in the UK, the following websites provide national and local information.

- NHS 24 (Scotland): www.nhs24.com
- Health in Wales: www.wales.nhs.uk
- HSCNI Services (Northern Ireland): http://online.hscni.net

These sites are the official sites for the National Health Service and provide links and signposting services to recognised organisations and charities.

About this information

This material was produced by PAPAA. Please be aware that research and development of treatments is ongoing.

For the latest information or any amendments to this material please contact us or visit our website www.papaa.org. The site contains information on treatments and includes patient experiences and case histories.

Original text written by Professor Neil McHugh, consultant rheumatologist, Royal National Hospital for Rheumatic Diseases, Bath, UK, in August 1996.

This edition reviewed and revised by Dr William Tillett, consultant rheumatologist, Royal National Hospital for
The Information Standard scheme was developed by the Department of Health to help the public identify trustworthy health and social care information easily. At the heart of the scheme is the standard itself – a set of criteria that defines good quality health or social care information and the methods needed to produce it. To achieve the standard, organisations have to show that their processes and systems produce information that is:

- accurate
- impartial
- balanced
- evidence-based
- accessible
- well-written.

The assessment of information producers is provided by independent certification bodies accredited by The United Kingdom Accreditation Service (UKAS). Organisations that meet The Standard can place the quality mark on their information materials and their website - a reliable symbol of quality and assurance.
The charity for people with psoriasis and psoriatic arthritis

PAPAA, the single identity of the Psoriatic Arthropathy Alliance and the Psoriasis Support Trust.

The organisation is independently funded and is a principal source of information and educational material for people with psoriasis and psoriatic arthritis in the UK.

PAPAA supports both patients and professionals by providing material that can be trusted (evidence-based), which has been approved and contains no bias or agendas.

PAPAA provides positive advice that enables people to be involved, as they move through their healthcare journey, in an informed way which is appropriate for their needs and any changing circumstances.
